**Abstract.** We study the ARC-PRESERVING SUBSEQUENCE (APS) problem with unlimited annotations. Given two arc-annotated sequences  $P$  and  $T$ , this problem asks if it is possible to delete characters from  $T$  to obtain  $P$ . Since even the unary version of APS is NP-hard, we used the framework of parameterized complexity, focusing on a parameterization of this problem where the parameter is the number of deletions we can make. We present a linear-time FPT algorithm for a generalization of APS, applying techniques originally designed to give an FPT algorithm for INDUCED SUBGRAPH ISOMORPHISM on interval graphs [12].

## 1 Introduction

Many important problems in computational biology are related to pattern matching in strings. The reason for this is that DNA, RNA, or protein molecules can be viewed as sequences of nucleotides or amino acids. To gain information about the behavior of such molecules, we often need to compare two sequences and somehow measure their similarity.

Given two sequences  $S_1$  and  $S_2$  over some alphabet, the task of the LONGEST COMMON SUBSEQUENCE (LCS) problem is to find the longest possible sequence that is the subsequence of both  $S_1$  and  $S_2$ . In other words, we are looking for a sequence  $C$  that can be obtained both from  $S_1$  and from  $S_2$  by deleting characters. This problem arises in many applications, like deciding if two species are biologically related, or whether two proteins are likely to exhibit similar functionalities related to three-dimensional structure (protein folding). Another classical problem, SUBSEQUENCE, asks if a sequence is the subsequence of another.

If we only want to deal with character sequences, LCS can be solved efficiently using dynamic programming. However, recent biological research suggests that we might lose relevant information if we model DNA, RNA, or protein molecules simply as sequences. The reason for this is that in such molecules, the shape and hence the functionality is greatly affected by chemical bonds between elements that might be far apart from each other in the sequence. *Arc-annotated sequences* are widely used to represent such bonds. In this model, any two elements (or *bases*) of a sequence can be connected to each other through an *arc*.

For two arc-annotated sequences  $S_1$  and  $S_2$ , the LONGEST ARC-PRESERVING COMMON SUBSEQUENCE or LAPCS asks for an arc-annotated sequence  $C$  of

maximum length that can be obtained both from  $S_1$  and from  $S_2$  by deleting bases together with all arcs incident to them. Since LAPCS is NP-complete even if the arc structures are highly restricted [5, 6, 10], researchers focused on polynomial-time solvable cases and approximation algorithms [5, 10, 9, 11].

Another direction of research is to use the parameterized complexity framework [4, 7]. This area deals with NP-hard problems by giving algorithms that have an acceptable running time on many relevant instances. An algorithm is *fixed-parameter tractable* (FPT) if its running time is bounded by  $f(k)n^{O(1)}$  for some function  $f$ , where  $n$  is the input size and  $k$  is the *parameter* associated with the input. The idea behind this definition is that the running time of an FPT algorithm remains tractable provided that the parameter has small value.

Parameterized complexity of LAPCS has already been studied, and FPT algorithms were presented for various parameterizations [1, 6]. An interesting parameterization is where the parameter is the number of deletions we are allowed to make in order to construct the common subsequence. This models a situation where we compare two sequences which are similar. An FPT algorithm was given in [1] with this parameter, but it only applies for a restricted case.

Unlike most previous results, we considered unlimited annotations where any two bases of a sequence can be connected by arcs. Though we could not give an FPT algorithm for this version of LAPCS, we were able to deal with the more simple ARC-PRESERVING SUBSEQUENCE problem (APS), the annotated analog of SUBSEQUENCE. Given two arc-annotated sequences  $P$  and  $T$ , the task of APS is to find out whether the pattern sequence  $P$  can be obtained by deleting some bases of the target sequence  $T$ , together with all the arcs incident to them. We remark that APS on its own is an interesting problem in computation biology, and has been widely studied in the literature. Its NP-hardness has been proved for numerous restricted cases [2], and polynomial-time algorithms have been presented [8, 3] for limited arc structures.

Here, we present an FPT algorithm for the unlimited APS, where the parameter is the number  $k$  of deletions allowed. Our algorithm runs in  $f(k)n$  time for some function  $f$  depending only on  $k$ , where  $n$  is the input size. In fact, we solve a generalization of APS where a few arcs can be deleted additionally. We mention that APS is W[1]-hard if the parameter is the length of the pattern [5].

The ideas and techniques applied here originate from an FPT algorithm solving a seemingly unrelated problem on interval graphs [12]. This algorithm answers the INDUCED SUBGRAPH ISOMORPHISM in FPT time: given two interval graphs  $G$  and  $H$  and a parameter  $k$ , is it possible to delete  $k$  vertices from  $G$  to obtain a graph isomorphic to  $H$ ? Our work shows that research connected to interval graphs can be useful for arc-annotated sequences as well.

## 2 Problem definition and notation

We denote  $\{1, \dots, n\}$  by  $[n]$ . We refer to the elements of a sequence  $S$  over an alphabet  $\Sigma$  as *bases*. We use  $S[i]$  to denote the  $i$ -th base of  $S$ , and  $|S|$  is the length of  $S$ .

Let  $S_P$  and  $S_T$  be two sequences over  $\Sigma$ . Let  $|S_P| = n_P$  and  $|S_T| = n_T$ , assume  $n_P \leq n_T$ . We say that  $S_P$  is a *subsequence* of  $S_T$  if  $S_P$  can be obtained by deleting bases from  $S_T$ , or equivalently, if there is a bijective mapping  $\varphi$  from  $[n_P]$  into a subset of  $[n_T]$  such that  $\varphi(i_1) < \varphi(i_2)$  for each  $1 \leq i_1 < i_2 \leq n_P$ , and  $S_P[i] = S_T[\varphi(i)]$  for each  $i \in [n_P]$ . We call such a  $\varphi$  an *alignment* of  $(S_P; S_T)$ . We write  $S^{\text{del}}(\varphi)$  to denote the set of bases that have to be deleted from  $S_T$  according to  $\varphi$ , i.e.  $S^{\text{del}}(\varphi) = [n_T] \setminus \bigcup_{i \in [n_P]} \varphi(i)$ .

An *arc-annotation*  $A$  of a sequence  $S$  of length  $n$  is a multiset of pairs of integers from  $[n]$ , where each pair  $(i_1, i_2) \in A$  satisfies  $i_1 < i_2$ . An *arc-annotated sequence*  $(S, A)$  is a sequence  $S$  together with an arc-annotation  $A$  for  $S$ . We say that an *arc*  $(i_1, i_2)$  *starts* at  $i_1$ , *ends* at  $i_2$ , and *connects* the positions  $i_1$  and  $i_2$  *incident* to it. We write  $A(i_1, i_2)$  for the multiplicity of the pair  $(i_1, i_2)$  in  $A$ , and we write  $A^+(i)$  and  $A^-(i)$  for the set of arcs starting or ending at  $i$ , respectively. Also, we let  $a^{\text{start}}$  and  $a^{\text{end}}$  to denote the starting and ending position of an arc  $a$ . We use  $|S, A|$  to denote the *size* of  $(S, A)$  in binary encoding.

Given two arc-annotated sequences  $(S_P, A_P)$  and  $(S_T, A_T)$ , we say that  $(S_P, A_P)$  is an *arc-preserving subsequence* of  $(S_T, A_T)$  if it can be obtained from  $(S_T, A_T)$  by deleting bases from it, i.e. there is an alignment  $\varphi$  of  $(S_P; S_T)$  such that  $A_P(i, j) = A_T(\varphi(i), \varphi(j))$  for any  $1 \leq i < j \leq |S_P|$ . Such an alignment is an *arc-preserving alignment* of  $(S_P, A_P; S_T, A_T)$ . Note that by deleting a base, we also mean the deletion of the arcs incident to it. Given two arc-annotated sequence  $P$  and  $T$ , the ARC-PRESERVING SUBSEQUENCE problem (APS) asks whether  $P$  is an arc-preserving subsequence of  $T$ .

We will deal with the following generalization of APS, which we call ALMOST APS or AAPS: given two arc-annotated sequences  $(S_P, A_P)$  and  $(S_T, A_T)$  and some  $k_a \in \mathbb{Z}$ , we ask if we can delete some bases from  $S_T$  (together with their incident arcs) and at most  $k_a$  arcs *in addition* to obtain  $(S_P, A_P)$ . Formally, we have to decide if there is a set  $A^{\text{del}}$  of at most  $k_a$  arcs in  $A_T$  such that  $(S_P, A_P)$  is an arc-preserving subsequence of  $(S_T, A_T \setminus A^{\text{del}})$ . We call  $\varphi$  a  $k_a$ -*alignment* for  $(S_P, A_P; S_T, A_T)$  if  $\varphi$  is an arc-preserving alignment of  $(S_P, A_P; S_T, A_T \setminus A^*)$  for some set  $A^*$  with  $|A^*| \leq k_a$ . Also, we let  $A^{\text{del}}(\varphi)$  to denote such an  $A^*$ .

Given a sequence  $S$ , let  $S^{\text{rev}}$  denote the reverse of  $S$ . For a position  $i$  of  $S$ , we will use  $i^{\text{rev}}$  to denote the position  $|S| - i + 1$  of  $S^{\text{rev}}$  corresponding to  $i$ . If  $A$  is an arc-annotation of  $S$ , then let  $A^{\text{rev}}$  denote the corresponding arc-annotation of  $S^{\text{rev}}$ , meaning  $A^{\text{rev}}(i_1, i_2) = A(i_2^{\text{rev}}, i_1^{\text{rev}})$ . We also let  $X^{\text{rev}} = \{i^{\text{rev}} \mid i \in X\}$  for any set  $X$  of positions in  $S$ .

If  $\varphi$  is a  $k_a$ -alignment for  $(S_P, A_P; S_T, A_T)$ , then  $\varphi^{\text{rev}}$  is the corresponding  $k_a$ -alignment for  $(S_P^{\text{rev}}, A_P^{\text{rev}}; S_T^{\text{rev}}, A_T^{\text{rev}})$ , i.e.  $\varphi^{\text{rev}}(i) = (\varphi(i^{\text{rev}}))^{\text{rev}}$  for each  $i$ .

Due to lack of space, we omit several proofs, see the Appendix for them.

### 3 Fixed-parameter tractability of APS

In this section we present an FPT algorithm for AAPS, a generalization of APS, with the parameterization where the parameters are the number of bases to delete and the number of arcs that can be deleted additionally.

ALMOST ARC-PRESERVING SUBSEQUENCE

Input: Two arc-annotated sequences  $(S_P, A_P)$  and  $(S_T, A_T)$ , and  $k_a \in \mathbb{Z}$ .

Parameters:  $k_a$  and  $k_b = |S_T| - |S_P|$ .

Task: decide whether  $(S_P, A_P)$  can be obtained from  $(S_T, A_T)$  by deleting  $k_b$  bases (together with their incident arcs) and  $k_a$  arcs in addition, i.e. whether there is a  $k_a$ -alignment  $\varphi$  for  $(S_P, A_P; S_T, A_T)$ .

Our aim is to prove the main result of the paper stated by Theorem 1.

**Theorem 1.** *There is an algorithm that solves any instance  $(S_P, A_P; S_T, A_T; k_a)$  of the ALMOST ARC-PRESERVING SUBSEQUENCE problem and runs in time  $k_b^{O(k_b^3 + k_b k_a)} |(S_T, A_T)|$  where  $k_b = |S_T| - |S_P|$ .*

### 3.1 Outline of the algorithm

To prove Theorem 1, we present an algorithm that uses a bounded search tree technique in order to construct a  $k_a$ -alignment step by step. In certain situations, the algorithm might branch on a bounded number of possibilities to proceed with. Since both the number of such branchings and the possible directions of a branching will be bounded in terms of  $k_a$  and  $k_b$ , the size of the resulting search tree will be bounded by a function of  $k_a$  and  $k_b$ .

Actually, the algorithm described here has the following behavior: given an instance of APS, consisting of the arc-annotated sequences  $(S_P, A_P)$  and  $(S_T, A_T)$ , and an integer  $k_a$ , it tries to construct a  $k_a$ -alignment  $\varphi$  for  $(S_P, A_P; S_T, A_T)$ . To do so, it fixes such a hypothetical solution  $\varphi$ , and looks for bases in  $S^{\text{del}}(\varphi)$  and arcs in  $A^{\text{del}}(\varphi)$ , which we will call *removable bases* and *removable arcs* of  $\varphi$ , resp. More precisely, our algorithm does one of the followings in linear time:

- it produces an **arc-preserving alignment**  $\psi$  for  $(S_P, A_P; S_T, A_T)$  (note that  $\psi$  is a  $k_a$ -alignment for  $(S_P, A_P; S_T, A_T)$  as well),
- it correctly **rejects** the instance, or
- it produces a **removable base** or a **removable arc** of  $\varphi$ .

In the last case, we can delete the given base or arc, and apply the algorithm to the obtained instance. Notice that one of the parameters  $k_a$  and  $k_b = |S_T| - |S_P|$  is decreased in the new instance. The presented algorithm will be shown to run in  $f(k_a, k_b) |(S_T, A_T)|$  time for some functions  $f$ , which therefore implies Theorem 1 by proving that AAPS can be solved in  $(k_a + k_b) f(k_a, k_b) |(S_T, A_T)|$  time.

Our algorithm might branch several times before producing an output as described above. Each such branch will be caused by guessing the answer to a question of the following form: given some position  $p$  in  $S_P$ , what is the value of the position  $\varphi(p)$ ?<sup>3</sup> We interpret these branchings in the usual framework of bounded search trees: a branching happens when we do not know the exact value of a certain variable (such as the value of  $\varphi(p)$  in the above example),

---

<sup>3</sup> In a few cases we will also need some additional branchings, described later on.

and thus we have to investigate every possible value. A certain branch examines one possible value of the variable, and it produces a correct output *if* the given variable indeed has the value associated with this branch. Since the examined cases always cover every possibilities, this implies that the output will be correct in at least one of the branches.

Although our algorithm seems to be a straightforward application of the bounded search tree methodology used frequently in parameterized algorithms, we had to overcome many difficulties to avoid any possibility of using an unbounded number of such guesses. The presented algorithm will apply considerably sophisticated methods to keep the search tree bounded.

### 3.2 Fragmentations and related concepts.

**Fragmentation.** To describe our knowledge of the partially constructed  $k_a$ -alignment we have, we introduce a data structure called *fragmentation*. By iteratively refining the fragmentation, we can get closer and closer to actually determine a  $k_a$ -alignment. We write  $|S_P| = n_P$  and  $|S_T| = n_T$ .

Recall that  $\varphi$  is a fixed  $k_a$ -alignment for  $(S_P, A_P; S_T, A_T)$ . For some  $1 \leq i_1 \leq i_2 \leq n_P$ , we define the *block*  $[i_1, i_2]$  in  $S_P$  to be the set of positions  $i_1, i_1+1, \dots, i_2$ , and we define blocks in  $S_T$  similarly. Given a set of  $f$  disjoint blocks  $\{[p_1^h, p_2^h] \mid h \in [f]\}$  in  $S_P$  and a set of  $f$  disjoint blocks  $\{[t_1^h, t_2^h] \mid h \in [f]\}$  in  $S_T$ , we let  $F_h = ([p_1^h, p_2^h], [t_1^h, t_2^h])$ . We say that  $\{F_h \mid h \in [f]\}$  is a *fragmentation* for  $\varphi$ , if

- $t_1^h \leq \varphi(p_1^h)$  and  $\varphi(p_2^h) \leq t_2^h$  for each  $h \in [f]$ , and
- $p_1^{h+1} = p_2^h + 1$  and  $t_1^{h+1} = t_2^h + 1$  for each  $h \in [f-1]$ .

We will call the element  $F_h$  for some  $h \in [f]$  a *fragment*. We define  $\sigma(F_h) = (t_2^h - t_1^h) - (p_2^h - p_1^h)$  and  $\delta(F_h) = t_1^h - p_1^h$ , which are both clearly non-negative integers. Note that  $\delta(F_{h+1}) = \delta(F_h) + \sigma(F_h)$  holds for each  $h \in [f-1]$ . We say that a position  $i \in [n_P]$  of  $S_P$  is *contained* in the fragment  $F_h$ , if  $p_1^h \leq i \leq p_2^h$ .

We will say that a fragment  $F$  is *trivial* if  $\sigma(F)$  is zero, and *non-trivial* otherwise. We also call a position of  $S_P$  trivial (or non-trivial) in a fragmentation, if the fragment containing it is trivial (or non-trivial, resp). Given fragmentation for  $\varphi$  and a position  $i$  in  $S_P$ , we will use the notation  $i_{\text{left}} = i + \delta(F)$  and  $i_{\text{right}} = i + \delta(F) + \sigma(F)$ , where  $F$  is the fragment containing  $i$ . Observe that

$$i_{\text{left}} \leq \varphi(i) \leq i_{\text{right}}$$

always holds. We will classify a position  $i$  of  $S_P$  as follows:

- If  $\varphi(i) = i_{\text{left}}$ , then  $i$  is *left-aligned*.
- If  $\varphi(i) = i_{\text{right}}$ , then  $i$  is *right-aligned*.
- If  $\varphi(i) = j$  such that  $i_{\text{left}} < j < i_{\text{right}}$ , then  $i$  is *skew*.

If  $i$  is trivial, then only  $\varphi(i) = i_{\text{left}} = i_{\text{right}}$  is possible. Thus, each trivial position must be both left- and right-aligned.

Notice that each fragment  $F$  must contain exactly  $\sigma(F)$  positions that are contained in  $S^{\text{del}}(\varphi)$ . This implies the following bounds.

**Proposition 2.** *If  $\mathcal{F}$  is a fragmentation for  $\varphi$ , then  $\sum_{F \in \mathcal{F}} \sigma(F) = k_b$ . In particular,  $\mathcal{F}$  can have at most  $k_b$  non-trivial fragments.*

A *marked fragmentation* for  $\varphi$  is a pair  $(\mathcal{F}, M)$  formed by a fragmentation  $\mathcal{F}$  for  $\varphi$  and a set  $M$  of positions in  $S_P$  such that each  $m \in M$  is a trivial position in  $\mathcal{F}$ . We say that the trivial positions contained in  $M$  are *marked*.

For a fragment  $F = ([p_1, p_2], [t_1, t_2])$  we let  $F^{\text{rev}} = ([p_2^{\text{rev}}, p_1^{\text{rev}}], [t_2^{\text{rev}}, t_1^{\text{rev}}])$ , hence a fragmentation  $\mathcal{F}$  for  $\varphi$  clearly yields a fragmentation  $\mathcal{F}^{\text{rev}} = \{F^{\text{rev}} \mid F \in \mathcal{F}\}$  for  $\varphi^{\text{rev}}$  as well. Note that if a position  $i$  of  $S_P$  is left-aligned (right-aligned) in  $\mathcal{F}$ , then the position  $i^{\text{rev}}$  is right-aligned (left-aligned, resp.) in  $\mathcal{F}^{\text{rev}}$ .

**Pairing arcs.** Given a position  $i$  in  $S_P$ , let us order the arcs  $c$  in  $A_P^+(i)$  increasingly according to their right endpoint  $c^{\text{end}}$ . Similarly, we order the arcs in  $A_P^-(i)$  increasingly according to their left endpoint. In both cases, we break ties arbitrarily. Also, we order the arcs in  $A_T^+(j)$  and  $A_T^-(j)$  in the same way for each position  $j$  in  $S_T$ . Now, we “pair” arcs in  $A_P^+(i)$  with arcs in  $A_T^+(i_{\text{left}})$ , and also arcs in  $A_P^-(i)$  with arcs in  $A_T^-(i_{\text{left}})$  according to their ranking in this ordering. To this end, we construct the sets  $R_{\text{left}}^+(i) \subseteq A_P^+(i) \times A_T^+(i_{\text{left}})$  and  $R_{\text{left}}^-(i) \subseteq A_P^-(i) \times A_T^-(i_{\text{left}})$  in the following way. We put a pair  $(c, d)$  into  $R_{\text{left}}^+(i)$ , if  $c \in A_P^+(i)$ ,  $d \in A_T^+(i_{\text{left}})$ , and  $c$  has the same rank (according to the above ordering) in  $A_P^+(i)$  as the rank of  $d$  in  $A_T^+(i_{\text{left}})$ . Similarly, we put a pair  $(c, d)$  into  $R_{\text{left}}^-(i)$ , if  $c \in A_P^-(i)$ ,  $d \in A_T^-(i_{\text{left}})$ , and  $c$  has the same rank in  $A_P^-(i)$  as the rank of  $d$  in  $A_T^-(i_{\text{left}})$ . In addition, we define the sets  $R_{\text{right}}^+(i)$  and  $R_{\text{right}}^-(i)$  analogously, by substituting  $i_{\text{right}}$  for  $i_{\text{left}}$  in the above definitions. The key properties of these sets are summarized below.

**Lemma 3.** *We know  $\varphi(c^{\text{end}}) = d^{\text{end}}$  and  $\varphi(c^{\text{start}}) = d^{\text{start}}$  in the following cases:*

- (1) *If  $(c, d) \in R_{\text{left}}^+(i)$  and  $|A_P^+(i)| = |A_T^+(i_{\text{left}})|$  for some left-aligned  $i$ .*
- (2) *If  $(c, d) \in R_{\text{left}}^-(i)$  and  $|A_P^-(i)| = |A_T^-(i_{\text{left}})|$  for some left-aligned  $i$ .*
- (3) *If  $(c, d) \in R_{\text{right}}^+(i)$  and  $|A_P^+(i)| = |A_T^+(i_{\text{right}})|$  for some right-aligned  $i$ .*
- (4) *If  $(c, d) \in R_{\text{right}}^-(i)$  and  $|A_P^-(i)| = |A_T^-(i_{\text{right}})|$  for some right-aligned  $i$ .*

**Arcs connecting two non-trivial fragments.** Given two non-trivial fragments  $F$  and  $H$  of a fragmentation with  $F$  preceding  $H$ , we define three disjoint subsets of those arcs of  $A_P$  that start in a position of  $F$  and end in a position of  $H$ . These sets will be denoted by  $\mathcal{L}(F, H)$ ,  $\mathcal{R}(F, H)$ , and  $\mathcal{X}(F, H)$ , and we construct them as follows. Suppose that  $c = (f, h) \in A_P$  for some  $f$  and  $h$  contained in  $F$  and  $H$ , respectively. We put  $c$  in exactly one of these three sets, if  $(c, d) \in R_{\text{left}}^-(h)$  for some arc  $d \in A_T$  such that  $f_{\text{left}} \leq d^{\text{start}} \leq f_{\text{right}}$ . If  $d^{\text{start}} = f_{\text{left}}$  then we put  $c$  into  $\mathcal{L}(F, H)$ , if  $d^{\text{start}} = f_{\text{right}}$  then we put  $c$  into  $\mathcal{R}(F, H)$ , and if  $f_{\text{left}} < d^{\text{start}} < f_{\text{right}}$  then we put  $c$  into  $\mathcal{X}(F, H)$ .

By Lemma 3, if the positions in  $H$  are left-aligned, then the left endpoints of the arcs in  $\mathcal{R}(F, H)$  must be right-aligned. Similarly, the left endpoints of the arcs in  $\mathcal{X}(F, H)$  must be skew in such a case. Proposition 4 states these observations in a precise manner. Since we would like to ensure each position to be left-aligned, we will try to get rid of the arcs in  $\mathcal{R}(F, H)$  and  $\mathcal{X}(F, H)$ .

**Proposition 4.** Let  $i$  be left-aligned,  $|A_P^-(i)| = |A_T^-(i_{\text{left}})|$ , and  $c \in A_P^-(i)$ .

- (1) If  $c \in \mathcal{L}(F, H)$ , then  $c^{\text{start}}$  is left-aligned.
- (2) If  $c \in \mathcal{R}(F, H)$ , then  $c^{\text{start}}$  is right-aligned.
- (3) If  $c \in \mathcal{X}(F, H)$ , then  $c^{\text{start}}$  is skew.

We say that two positions  $f_1, f_2 \in [n_P]$  are *conflicting* for  $(F, H)$ , if  $f_1 \leq f_2$ ,  $A_P^+(f_1) \cap \mathcal{R}(F, H) \neq \emptyset$  and  $A_P^+(f_2) \cap \mathcal{L}(F, H) \neq \emptyset$ . In such a case, we say that any  $h \geq \max\{h_1, h_2\}$  in  $H$  is *conflict-inducing* for  $(F, H)$  (and for the conflicting pair  $(f_1, f_2)$ ), where  $h_1$  denotes the minimal position for which  $(f_1, h_1) \in \mathcal{R}(F, H)$ , and  $h_2$  denotes the minimal position for which  $(f_2, h_2) \in \mathcal{L}(F, H)$ . Notice that if such a conflict-inducing  $h$  is left-aligned, then both  $h_1$  and  $h_2$  are left-aligned. By Proposition 4, this implies that  $f_1$  is right-aligned and  $f_2$  is left-aligned. But since  $f_1$  precedes  $f_2$ , this cannot happen. This implies the following observation.

**Proposition 5.** If a position  $h$  is conflict-inducing for  $(F, H)$  in a given fragmentation, then  $h$  cannot be left-aligned.

In addition, if  $\mathcal{L}(F, H) \neq \emptyset$ , then let  $L^{\max}(F, H)$  denote the largest position  $f$  in  $F$  for which  $A_P^+(f) \cap \mathcal{L}(F, H) \neq \emptyset$ . Let the *L-critical position* for  $(F, H)$  be the smallest position  $h$  contained in  $H$  for which  $(L^{\max}(F, H), h) \in \mathcal{L}(F, H)$ . Similarly, if  $\mathcal{R}(F, H) \neq \emptyset$ , then let  $R^{\min}(F, H)$  denote the smallest position  $f$  in  $F$  for which  $A_P^+(f) \cap \mathcal{R}(F, H) \neq \emptyset$ . Also, let the *R-critical position* for  $(F, H)$  be the smallest position  $h$  in  $H$  for which  $(R^{\min}(F, H), h) \in \mathcal{R}(F, H)$ .

Now, a position  $h$  in  $H$  is *LR-critical* for  $(F, H)$ , if either  $h$  is the R-critical position for  $(F, H)$  and  $\mathcal{L}(F, H) = \emptyset$ , or  $h = \max\{h_L, h_R\}$  where  $h_L$  is the L-critical and  $h_R$  is the R-critical position for  $(F, H)$ . Note that both cases require  $\mathcal{R}(F, H) \neq \emptyset$ . Moreover,  $H$  contains an LR-critical position for  $(F, H)$ , if and only if  $\mathcal{R}(F, H) \neq \emptyset$ . Intuitively, if an LR-critical position in  $H$  is left-aligned, then this implies that some position in  $F$  is right-aligned.

Note that the definitions of the sets  $\mathcal{L}(F, H)$ ,  $\mathcal{R}(F, H)$ , and  $\mathcal{X}(F, H)$  together with the definitions connected to them as described above depend on the given fragmentation, so whenever the fragmentation changes, these must be adjusted appropriately as well. (In particular, arcs in  $\mathcal{L}(F, H)$ ,  $\mathcal{R}(F, H)$ , and  $\mathcal{X}(F, H)$  must start and end in two different non-trivial fragments.)

**Properties 1-9.** Let  $(\mathcal{F}, M)$  be a marked fragmentation for  $\varphi$ . Our aim is to ensure that the properties given below hold for each position in  $S_P$ . Intuitively, these properties mirror the expectation that every position should be left-aligned. Note that although we cannot decide whether  $(\mathcal{F}, M)$  is a correct marked fragmentation without knowing the  $k_a$ -alignment  $\varphi$ , we are able to check whether these properties hold for some position  $i$  in  $(\mathcal{F}, M)$ .

**Property 1:**  $S_P[i] = S_T[i_{\text{left}}]$ .

**Property 2:** If  $i$  is non-trivial, then  $|A_P^+(i)| = |A_T^+(i_{\text{left}})|$  and  $|A_P^-(i)| = |A_T^-(i_{\text{left}})|$ .

**Property 3:** If  $i$  is non-trivial, then  $A_P(y, i) = A_T(y_{\text{left}}, i_{\text{left}})$  for any  $y < i$  contained in the same fragment as  $i$ .

**Property 4:** If  $i$  is non-trivial, then for every  $(c, d) \in R_{\text{left}}^+(i)$  such that  $c^{\text{end}} = y$  is non-trivial,  $y_{\text{left}} \leq d^{\text{end}} \leq y_{\text{right}}$  holds. Also, for every  $(c, d) \in R_{\text{left}}^-(i)$  such that  $c^{\text{start}} = y$  is non-trivial,  $y_{\text{left}} \leq d^{\text{start}} \leq y_{\text{right}}$  holds.

**Property 5:** No arc in  $\mathcal{X}(F, H)$  for some  $(F, H)$  ends at  $i$ .

**Property 6:**  $i$  is not conflict-inducing for any  $(F, H)$ .

**Property 7:**  $i$  is not LR-critical for any  $(F, H)$ .

**Property 8:** If  $i$  is non-trivial, then for every  $(c, d) \in R_{\text{left}}^+(i)$  such that  $c^{\text{end}} = y$  is non-trivial,  $d^{\text{end}} = y_{\text{left}}$  holds. Also, for every  $(c, d) \in R_{\text{left}}^-(i)$  such that  $c^{\text{start}} = y$  is non-trivial,  $d^{\text{start}} = y_{\text{left}}$  holds.

**Property 9:** If  $i$  is non-trivial, then for each marked position  $m \in M$ ,  $A_P(i, m) = A_T(i_{\text{left}}, m_{\text{left}})$  holds if  $m > i$ , and  $A_P(m, i) = A_T(m_{\text{left}}, i_{\text{left}})$  holds if  $m < i$ .

Observe that each of these properties depend on the fragmentation  $\mathcal{F}$ , and Property 9 depends on the set of marked positions  $M$  as well. Also, if some property holds for a position  $i$  in  $(\mathcal{F}, M)$ , then this does not imply that the property holds for  $i^{\text{rev}}$  in  $(\mathcal{F}^{\text{rev}}, M^{\text{rev}})$ , as most of these properties are not symmetric. For example,  $i_{\text{left}}$  and  $i_{\text{right}}$  both have a different meaning in the fragmentation  $\mathcal{F}$  and in  $\mathcal{F}^{\text{rev}}$ . We say that a position  $i \in [n_P]$  *violates* Property  $\ell$  ( $1 \leq \ell \leq 9$ ) in a marked fragmentation  $(\mathcal{F}, M)$ , if Property  $\ell$  does not hold for  $i$  in  $(\mathcal{F}, M)$ .

If the first eight properties hold for each position both in  $(\mathcal{F}, M)$  and in  $(\mathcal{F}^{\text{rev}}, M^{\text{rev}})$ , then we say that  $(\mathcal{F}, M)$  is *8-proper*. We say that  $(\mathcal{F}, M)$  is *proper*, if it is 8-proper and Property 9 holds for each position of  $S_P$  in  $(\mathcal{F}, M)$ . Note that we do not care whether Property 9 holds for the positions in the reversed instance, so  $(\mathcal{F}, M)$  is proper even if Property 9 does not hold in  $(\mathcal{F}^{\text{rev}}, M^{\text{rev}})$ .

### 3.3 Description of the algorithm

We start with a marked fragmentation where  $M = \emptyset$  and the fragmentation contains only the unique fragment  $([1, n_P], [1, n_T])$ , which is non-trivial if  $k_b > 0$ . Given a marked fragmentation  $(\mathcal{F}, M)$ , we do the following: if one of Properties 1, 2,  $\dots$ , 9 does not hold for some position  $i$  in  $(\mathcal{F}, M)$  or one of the first eight properties does not hold for some  $i$  in the reversed marked fragmentation  $(\mathcal{F}^{\text{rev}}, M^{\text{rev}})$ , then we will either **reject** the instance, output a **removable base** of  $\varphi$ , or modify the given marked fragmentation. If the given marked fragmentation is proper, the algorithm returns an output using Lemmas 9 and 10.

To do this, in each step we choose the first property violated by a position either in  $(\mathcal{F}, M)$  or in  $(\mathcal{F}^{\text{rev}}, M^{\text{rev}})$ . Observe that we can assume w.l.o.g. that there is an  $\ell$  ( $1 \leq \ell \leq 9$ ) such that Properties 1,  $\dots$ ,  $\ell - 1$  hold for each position both in  $(\mathcal{F}, M)$  and in  $(\mathcal{F}^{\text{rev}}, M^{\text{rev}})$ , but Property  $\ell$  is violated by a position in  $S_P$  in  $(\mathcal{F}, M)$ , otherwise we simply reverse the instance. (We only reverse it if this condition is not true.)

Given  $\ell$ , the algorithm takes the first position  $i$  violating Property  $\ell$ , and branches on choosing  $\varphi(i)$  according to  $i_{\text{left}} \leq \varphi(i) \leq i_{\text{right}}$ . By Proposition 2, this results in at most  $k_b + 1$  directions. Next, the algorithm handles each of the cases in a different manner, according to whether  $i$  turns out to be left-aligned, right-aligned, or skew. We consider these cases in a general way that is essentially independent from  $\ell$ , and mainly relies on the type of  $i$ . We suppose that  $i$  is contained in a fragment  $F^i = ([p_1, p_2], [t_1, t_2])$ .

**Extremal cases.** Assume that  $i = p_1$  and  $i$  is skew or right-aligned, or  $i = p_2$  and  $i$  is skew or left-aligned. In these cases, we can find at least one **removable base** of  $\varphi$ . First, if  $i = p_1$  and  $i$  is skew or right-aligned, then each base  $S_T[j]$  must be deleted for each  $j$  where  $t_1 \leq j < \varphi(i)$ . Second, if  $i = p_2$  and  $i$  is skew or left-aligned, then  $S_T[j]$  must be deleted for each  $j$  where  $\varphi(i) < j \leq t_2$ .

**Skew position.** Suppose that  $i > p_1$  and  $j$  is skew, meaning that  $\varphi(i) = j$  for some  $j$  with  $i_{\text{left}} < j < i_{\text{right}}$ . In this case, we can divide the fragment  $F^i$ , or more precisely, we can delete  $F^i$  from the fragmentation  $\mathcal{F}$  and add the new fragments  $([p_1, i-1], [t_1, j-1])$  and  $([i, p_2], [j, t_2])$ . Note that the newly introduced fragments are non-trivial by the bounds on  $j$ . We also modify  $M$  by declaring every trivial position of the fragmentation to be marked (no matter whether it was marked or not before). Observe that the number of non-trivial fragments increases in this step. By Proposition 2, this can happen at most  $k_b - 1$  times.

**Left-aligned position.** Lemma 6 summarizes our results that show how to deal with the case when  $i$  is left-aligned and  $i < p_2$ . The proof of this lemma is essential in the correctness of our algorithm.

**Lemma 6.** *Suppose that Property  $\ell$  ( $1 \leq \ell \leq 9$ ) does not hold for some  $i \in [n_P]$  in the marked fragmentation  $(\mathcal{F}, M)$ , but all the previous properties hold for each position both in  $(\mathcal{F}, M)$  and in  $(\mathcal{F}^{\text{rev}}, M^{\text{rev}})$ . If  $i$  is left-aligned, then depending on  $\ell$ , we can do one of the followings in linear time (without any branchings):*

- A) *reject correctly,*
- B) *output a removable arc of  $\varphi$ ,*
- C) *find that  $i$  is incident to a removable arc of  $\varphi$  (this only happens if  $\ell = 2$ ),*
- D) *produce a skew position  $i'$ , or*
- E) *produce a set  $N$  of at most  $2k_b - 1$  positions in  $S_T$  such that  $N \cap S^{\text{del}}(\varphi) \neq \emptyset$ .*

In Case A or B, we **reject** or output a **removable arc** of  $\varphi$ .

In Case C, we put the non-trivial position  $i$  in a set  $W$ , which will only store positions in  $S_T$  that are incident to a removable arc of  $\varphi$ . (We set  $W = \emptyset$  initially.) Whenever Case C happens, we examine whether  $|W| \leq 2k_a$ . If not, then we **reject** the input. This is correct, since there can be at most  $k_a$  removable arcs of  $\varphi$ , and each such arc is incident to two bases.

If  $|W| \leq 2k_a$  holds, then we modify the given fragmentation, replacing  $F^i$  by new fragments  $F_1 = ([p_1, i], [t_1, i_{\text{left}}])$  and  $F_2 = ([i+1, p_2], [i_{\text{left}}+1, t_2])$ . By  $\varphi(i) = i_{\text{left}}$ , this yields a fragmentation for  $\varphi$ . Note that  $F_1$  is trivial and  $F_2$  is non-trivial. We mark each position of  $F_2$ , putting them into  $M$ . We refer to this operation as a *left split* at  $i$ . Since  $i$  becomes trivial in  $F_1$ , each position can be placed into  $W$  at most once. Thus, Case C can happen at most  $2k_a$  times without rejecting.

In Cases D and E, we might branch into a bounded number of additional branches. In Case D, we branch on those choices of  $\varphi(i')$  where  $i'$  is indeed skew, which means  $\sigma(F^i) - 1 \leq k_b - 1$  directions, and we handle each branch according to the way described above (dividing one fragment at the skew position  $i'$ ). In Case E, we branch into at most  $2k_b - 1$  directions on choosing a **removable base** of  $\varphi$  from  $N$  and outputting it.

Note that Case D or E can happen at most  $k_b$  times, by our observation that a skew position can only be found at most  $k_b - 1$  times.

We remark that if  $i$  is trivial, then we treat it as left-aligned.

**Right-aligned position.** Suppose that  $i > p_1$  and  $i$  is right-aligned. In this case, we replace  $F^i$  by new fragments  $F_1 = ([p_1, i - 1], [t_1, i_{\text{right}} - 1])$  and  $F_2 = ([i, p_2], [i_{\text{right}}, t_2])$ . This yields a fragmentation where  $F_1$  is non-trivial and  $F_2$  is trivial. We refer to this operation as performing a *right split* at  $j$ . If this happens because  $i$  violated Property  $\ell$  for some  $\ell \leq 8$ , then we mark every trivial position (including those contained in  $F_2$ ), by putting them into  $M$ . If  $\ell = 9$ , then we do not modify  $M$ , so the trivial positions of  $F_2$  will not be marked.

The above process either produces a **removable base** of  $\varphi$ , **rejects** correctly, or ends by providing a marked fragmentation that is proper. In the remaining steps of the algorithm, the set  $M$  will never be modified, and the only possible modification of the actual fragmentation will be to perform a right split.

Given a proper marked fragmentation  $(\mathcal{F}, M)$ , we make use of Lemma 9 below. This lemma gives sufficient conditions to do one of the followings.

- Find out that some non-trivial position  $i$  is right-aligned. In this case, we perform a right split at  $i$  in the actual fragmentation.
- Find a **removable arc** of  $\varphi$ .
- **Reject** correctly.

Our algorithm applies Lemma 9 repeatedly, until it either stops (by rejecting or outputting a removable arc of  $\varphi$ ), or finds that none of the conditions of Lemma 9 apply. Before stating this lemma, we need two more important observations. First, Lemma 7 shows that the repeated application of Lemma 9 results in a proper fragmentation. Second, Lemma 8 states some useful invariants that hold for each fragmentation obtained by us after a proper fragmentation is achieved.

**Lemma 7.** *If  $(\mathcal{F}, M)$  is proper and  $\mathcal{F}'$  is obtained by applying an arbitrary number of right splits to  $\mathcal{F}$ , then  $(\mathcal{F}', M)$  is proper as well.*

**Lemma 8.** *Let  $(\mathcal{F}, M)$  be a 8-proper marked fragmentation whose trivial positions are all marked. Suppose that  $\mathcal{F}'$  is obtained by applying an arbitrary number of right splits to the fragmentation  $\mathcal{F}$ .*

- (1) *For each  $i$  that is not marked ( $i \in [n_P] \setminus M$ ), both  $A_P^+(i) = A_T^+(i_{\text{right}})$  and  $A_P^-(i) = A_T^-(i_{\text{right}})$  hold in  $(\mathcal{F}', M)$ .*
- (2) *Suppose that neither  $i$  nor  $j$  is marked ( $i, j \in [n_P] \setminus M$ ) and  $c = (i, j) \in A_P$ . If  $(c, d) \in R_{\text{right}}^+(i)$  for some  $d \in A_T^+(i_{\text{right}})$ , then  $d^{\text{end}} = j_{\text{right}}$ . Similarly, if  $(c, d) \in R_{\text{right}}^-(j)$  for some  $d \in A_T^-(j_{\text{right}})$ , then  $d^{\text{start}} = i_{\text{right}}$ .*

Now, we can state Lemma 9.

**Lemma 9.** *Let  $(\mathcal{F}, M)$  be a proper marked fragmentation for  $\varphi$  obtained by our algorithm, and let  $a, b \in [n_P]$ .*

- (i) *Suppose that  $a$  is trivial but not marked and  $b$  is non-trivial. If  $(a, b) \in A_P$*

or  $(b, a) \in A_P$ , then  $b$  is right-aligned.

(ii) If  $a$  and  $b$  are trivial,  $a < b$  and  $A_P(a, b) \neq A_T(a_{\text{left}}, b_{\text{left}})$ , then we can either **reject** or output a **removable arc** of  $\varphi$ .

After applying Lemma 9 repeatedly, the algorithm either stops by rejecting or outputting a removable arc of  $\varphi$ , or it finds that neither of the conditions (i) and (ii) of Lemma 9 holds. Let  $(\mathcal{F}, M)$  be the final marked fragmentation obtained. Note that the algorithm does not modify the set  $M$  of marked trivial positions when applying Lemma 9, and it can only modify the actual fragmentation by performing a right split. Hence, Lemma 7 yields that  $(\mathcal{F}, M)$  is proper.

Using  $(\mathcal{F}, M)$ , Lemma 10 claims that we can find an arc-preserving alignment for  $(S_P, A_P; S_T, A_T)$  in linear time. Hence, the final step of our algorithm, finishing its description, is to output this **arc-preserving alignment**.

**Lemma 10.** *Let  $(\mathcal{F}, M)$  be a proper marked fragmentation for  $\varphi$  obtained by the algorithm. If none of the conditions of Lemma 9 holds, then we can produce an **arc-preserving alignment**  $\psi$  for  $(S_P, A_P; S_T, A_T)$  in linear time.*

*Proof.* We show that defining  $\psi(i) = i_{\text{left}}$  for each position  $i \in [n_P]$  fulfills the requirements. For this, we have to prove  $S_P[i] = S_T[i_{\text{left}}]$  for each position  $i \in [n_P]$ , and  $A_P(i, j) = A_T(i_{\text{left}}, j_{\text{left}})$  for each two positions  $i \neq j \in [n_P]$ .

First, as Property 1 holds for each position in  $\mathcal{F}$ , we know  $S_P[i] = S_T[i_{\text{left}}]$  for each  $i \in [n_P]$ . It remains to show  $A_P(i, j) = A_T(i_{\text{left}}, j_{\text{left}})$  for each  $i \neq j \in [n_P]$ . If both  $i$  and  $j$  are trivial positions, then this is true because the conditions of (ii) in Lemma 9 do not apply. If both  $i$  and  $j$  are non-trivial, then  $A_P(i, j) = A_T(i_{\text{left}}, j_{\text{left}})$  again holds, by Properties 2 and 8 for  $j$ . Now, if  $i$  is non-trivial but  $j$  is trivial and marked (or vice versa), then Property 9 implies the required equality. Finally, if one of  $i$  and  $j$  is non-trivial and the other one is trivial but not marked, then  $A_P(i, j) = 0$  holds, since (i) of Lemma 9 is not applicable.  $\square$

### 3.4 Analysis of the algorithm

In this section, we give some hints how to analyse the running time of the presented algorithm. The following lemma, stating the key properties of the our algorithm, proves Theorem 1.

**Lemma 11.** *Let  $(S_P, A_P, S_T, A_T, k_a)$  be the given instance of APS. The presented algorithm branches into at most  $f(k_a, k_b)$  directions in total for some function  $f$  such that in each branch it does one of the followings (supposing that the conditions of the given branch do hold):*

- it gives an **arc-preserving alignment**  $\psi$  of  $(S_P, A_P; S_T, A_T)$ ,
- it correctly **rejects** the instance, or
- it outputs a **removable base** or a **removable arc** of  $\varphi$ .

Moreover, each branch takes linear time in the size of the input.

Although we do not prove Lemma 11 due to lack of space, we give the most important definitions used in the proof.

Given a fragmentation  $\mathcal{F}$  for  $\varphi$ , a fragment  $F \in \mathcal{F}$ , and some  $\ell$  ( $1 \leq \ell \leq 8$ ), let  $\pi(\mathcal{F}, F, \ell)$  be 1 if Property  $\ell$  holds for each position  $i$  in  $F$ , and 0 otherwise. Let  $N(\mathcal{F})$  denote the set of non-trivial fragments in  $\mathcal{F}$ . We define the *measure*  $\mu(\mathcal{F})$  of a given fragmentation  $\mathcal{F}$  for  $\varphi$  as follows:

$$\mu(\mathcal{F}) = \sum_{1 \leq \ell \leq 8} \left( \sum_{F \in N(\mathcal{F})} \pi(\mathcal{F}, F, \ell) + \sum_{F \in N(\mathcal{F}^{\text{rev}})} \pi(\mathcal{F}^{\text{rev}}, F, \ell) \right).$$

Note that  $\mu(\mathcal{F}) = \mu(\mathcal{F}^{\text{rev}})$  is trivial, so reversing a fragmentation does not change its measure. The importance of this definition is shown by Lemma 12.

**Lemma 12.** *Let  $\mathcal{F}_1, \dots, \mathcal{F}_t, \mathcal{F}_{t+1}$  be a series of fragmentations such that for each  $i \in [t]$  the algorithm obtains  $\mathcal{F}_{i+1}$  from  $\mathcal{F}_i$  by applying a left or a right split at a position  $j_i$  violating Property  $\ell_i$  in  $\mathcal{F}_i$ . Then (1)  $\mu(\mathcal{F}_{i+1}) \geq \mu(\mathcal{F}_i)$  for each  $i \in [t]$ , and (2) if  $\mu(\mathcal{F}_1) = \mu(\mathcal{F}_t)$ , then  $t \leq k_b$  holds.*

## Appendix

### A. The proof of Lemma 6

Let us prove Lemma 6. Suppose that Property  $\ell$  ( $1 \leq \ell \leq 9$ ) does not hold for some  $i \in [n_P]$  in the marked fragmentation  $(\mathcal{F}, M)$ , but all the previous properties hold for each position both in  $(\mathcal{F}, M)$  and in  $(\mathcal{F}^{\text{rev}}, M^{\text{rev}})$ . Suppose also that  $i$  is left-aligned, i.e.  $\varphi(i) = i_{\text{left}}$ . Below we describe the detailed steps of our algorithm depending on the property that is violated by  $i$ .

**Property 1:**  $S_P[i] = S_T[i_{\text{left}}]$ .

If  $i$  violates Property 1, then  $S_P[i] \neq S_T[i_{\text{left}}]$ . But since  $\varphi$  is a  $k_a$ -alignment of  $(S_P, A_P; S_T, A_T)$ , this contradicts  $\varphi(i) = i_{\text{left}}$ . Thus, we can **reject**.

**Property 2:** If  $i$  is non-trivial, then  $|A_P^+(i)| = |A_T^+(i_{\text{left}})|$  and  $|A_P^-(i)| = |A_T^-(i_{\text{left}})|$ .

By  $\varphi(i) = i_{\text{left}}$  and since  $\varphi$  is a  $k_a$ -alignment, the number of arcs in  $A_T$  starting (or ending) at  $i_{\text{left}}$  must be at least the number of arcs in  $A_P$  starting (or ending, resp.) in  $i$ . Thus, if  $|A_P^+(i)| > |A_T^+(i_{\text{left}})|$  or  $|A_P^-(i)| > |A_T^-(i_{\text{left}})|$ , then we can **reject**. If  $|A_P^+(i)| < |A_T^+(i_{\text{left}})|$  or  $|A_P^-(i)| < |A_T^-(i_{\text{left}})|$ , then we know that at least one arc starting or ending in  $i$  must be contained in  $A^{\text{del}}(\varphi)$ , although we do not know which one. In this case, we provide  $i$  as a position incident to a removable arc of  $\varphi$ .

**Property 3:** If  $i$  is non-trivial, then  $A_P(y, i) = A_T(y_{\text{left}}, i_{\text{left}})$  for any  $y < i$  contained in the same fragment as  $i$ .

As  $\varphi(i) = i_{\text{left}}$  and  $y$  is contained in the same fragment as  $i$ , we also get  $\varphi(y) = y_{\text{left}}$ . Thus,  $A_P(y, i) > A_T(y_{\text{left}}, i_{\text{left}})$  means that we can reject, and  $A_P(y, i) < A_T(y_{\text{left}}, i_{\text{left}})$  means that at least one arc  $(y_{\text{left}}, i_{\text{left}})$  is a **removable arc**.

**Property 4:** If  $i$  is non-trivial, then for every  $(c, d) \in R_{\text{left}}^+(i)$  such that  $c^{\text{end}} = y$  is non-trivial,  $y_{\text{left}} \leq d^{\text{end}} \leq y_{\text{right}}$  holds. Also, for every  $(c, d) \in R_{\text{left}}^-(i)$  such that  $c^{\text{start}} = y$  is non-trivial,  $y_{\text{left}} \leq d^{\text{start}} \leq y_{\text{right}}$  holds.

Suppose that  $i$  violates Property 4, because  $(c, d) \in R_{\text{left}}^+(i)$  such that  $c^{\text{end}} = y$  is non-trivial, but  $y_{\text{left}} \leq d^{\text{end}} \leq y_{\text{right}}$  does not hold. We show that we can reject in this case. As Property 2 holds for  $i$ ,  $|A_P^+(i)| = |A_T^+(i_{\text{left}})|$ . As  $i$  is left-aligned, we get  $\varphi(c^{\text{end}}) = \varphi(y) = d^{\text{end}}$  by Lemma 3. By  $y_{\text{left}} \leq \varphi(y) \leq y_{\text{right}}$  we get a contradiction. Supposing the other case leads to the same result, hence we can **reject** in both cases.

**Property 5:** No arc in  $\mathcal{X}(F, H)$  for some  $(F, H)$  ends at  $i$ .

Suppose that Property 5 does not hold for  $i$ , so there is an arc  $(y, i) \in \mathcal{X}(F, H)$  for some  $y < i$ . As  $i$  is left-aligned, Proposition 4 implies that  $y$  is skew, so we can return  $y$  as a skew position.

**Property 6:**  $i$  is not conflict-inducing for any  $(F, H)$ .

Suppose that  $i$  violates Property 6 because it is conflict-inducing for some  $(F, H)$  and for some conflicting pair of positions  $(y_1, y_2)$ . Let  $j_1$  be the minimal position for which there is an arc  $(y_1, j_1) \in \mathcal{R}(F, H) \neq \emptyset$ , and let  $j_2$  be the minimal position for which there is an arc  $(y_2, j_2) \cap \mathcal{L}(F, H) \neq \emptyset$ . Since  $i \geq \max\{j_1, j_2\}$  is in the same fragment as  $j_1$  and  $j_2$  and  $i$  is left-aligned, we know that both  $j_1$  and  $j_2$  are left-aligned as well. By Proposition 4, this implies that  $y_1$  is right-aligned and  $y_2$  is left-aligned. But since  $y_1 \leq y_2$  (because  $(y_1, y_2)$  is conflicting), this is a contradiction, so we can **reject**.

**Property 7:**  $i$  is not LR-critical for any  $(F, H)$ .

Suppose that  $i$  is LR-critical for some  $(F, H)$ . In this case,  $R^{\min}(F, H) = y^R$  is a position contained in  $F$ . Since  $i$  is left-aligned, the R-critical position for  $(F, H)$  is also left-aligned, hence Proposition 4 yields that  $y^R$  is right-aligned. Let  $p_1$  be the first position of  $[n_P]$  contained in  $F$ , and let  $t_1 = (p_1)_{\text{left}}$ . We claim that one of the bases of  $S_T$  in the block  $[\max(t_1, y^R_{\text{left}} - \sigma(F) + 1), y^R_{\text{right}} - 1]$  must be a removable base. If this is true, then we can return the set of these at most  $2\sigma(F) - 1 \leq 2k_b - 1$  bases.

First, if  $y^R < p_1 + \sigma(F)$ , we get  $\max(t_1, y^R_{\text{left}} - \sigma(F) + 1) = t_1$  by  $y^R_{\text{left}} - \sigma(F) < (p_1)_{\text{left}} = t_1$ . Using  $\varphi(p_1) \geq t_1$  and  $\varphi(y^R) = y^R_{\text{right}}$ , the pigeonhole principle yields that some position in  $[t_1, y^R_{\text{right}} - 1]$  must be contained in  $S^{\text{del}}(\varphi)$ , which proves our claim.

Second, suppose  $y^R \geq p_1 + \sigma(F)$ . In this case, there exists a position  $j$  for which  $j_{\text{right}} = y^R_{\text{left}}$ . By Properties 2 and 4 for  $y^R$ , we know that there is an arc in  $A_T^+(y^R_{\text{left}})$  that ends in the fragment  $H$ . Using Properties 2 and 4 again for  $j^{\text{rev}}$  in the reversed instance, we know that there must be an arc  $c$  in  $A_P^+(j)$  that ends in the fragment  $H$ . Clearly,  $c \in \mathcal{L}(F, H) \cup \mathcal{R}(F, H) \cup \mathcal{X}(F, H)$  must hold by Property 4 for  $j$ . Observe that  $c \notin \mathcal{X}(F, H)$ , as Property 5 holds for every position in  $[n_P]$ . Also,  $c \notin \mathcal{R}(F, H)$  by the definition of  $y^R = R^{\min}(F, H)$ . Thus, we know that  $c \in \mathcal{L}(F, H)$ , implying  $y^L = L^{\max}(F, H) \geq j$  as well. As Property 6 holds for each position, we also have  $y^L < y^R$ .

Since  $i$  is LR-critical, at least one arc of  $\mathcal{L}(F, H)$  starting at  $y^L$  must end at a position  $i'$  not greater than  $i$ . Clearly, as  $i$  is left-aligned we get that  $i'$  is left-aligned as well. By Proposition 4, this means that  $y^L$  is left-aligned too. Now, by  $\varphi(y^L) = y^L_{\text{left}}$  and  $\varphi(y^R) = y^R_{\text{right}}$ , we obtain that some position in  $[y^L_{\text{left}} + 1, y^R_{\text{right}} - 1]$  must be contained in  $S^{\text{del}}(\varphi)$ . Using  $\max(t_1, y^R_{\text{left}} - \sigma(F) + 1) = y^R_{\text{left}} - \sigma(F) + 1 = j_{\text{right}} - \sigma(F) + 1 = j_{\text{left}} + 1 \leq y^L_{\text{left}} + 1$ , this proves our claim.

**Property 8:** If  $i$  is non-trivial, then for every  $(c, d) \in R^+_{\text{left}}(i)$  such that  $c^{\text{end}} = y$  is non-trivial,  $d^{\text{end}} = y_{\text{left}}$  holds. Also, for every  $(c, d) \in R^-_{\text{left}}(i)$  such that  $c^{\text{start}} = y$  is non-trivial,  $d^{\text{start}} = y_{\text{left}}$  holds.

If Property 8 does not hold for  $i$ , then by Properties 2 and 4 either  $A_P^-(i)$  or  $A_P^+(i)$  must contain an arc in  $\mathcal{R}(F, H) \cup \mathcal{X}(F, H)$  for some  $(F, H)$ . But this means that Property 5 or 7 is violated, a contradiction. Thus, we can correctly **reject**.

**Property 9:** If  $i$  is non-trivial, then for each marked position  $m \in M$ ,  $A_P(i, m) = A_T(i_{\text{left}}, m_{\text{left}})$  holds if  $m > i$ , and  $A_P(m, i) = A_T(m_{\text{left}}, i_{\text{left}})$  holds if  $m < i$ .

Suppose that  $i$  violates Property 9, because  $A_P(i, m) \neq A_T(i_{\text{left}}, m_{\text{left}})$  for some  $m > i$ . (The case  $m < i$  is analogous.) Since  $m$  is trivial,  $\varphi(m) = m_{\text{left}}$ . Considering  $\varphi(i) = i_{\text{left}}$ , we get that if  $A_P(i, m) > A_T(i_{\text{left}}, m_{\text{left}})$ , implies that we can **reject** the instance. On the other hand, if  $A_P(i, m) < A_T(i_{\text{left}}, m_{\text{left}})$  then we can output a **removable arc**  $(i_{\text{left}}, m_{\text{left}})$ .

## B. Proving the correctness of our algorithm

Here we present all remaining proofs showing that our algorithm is correct.

*Proof (of Lemma 3).* We only show (1), as all the other statements are analogous. To this end, recall that as  $i$  is left-aligned,  $\varphi(i) = i_{\text{left}}$ . Note that  $(c, d) \in R_{\text{left}}^+(i)$  directly implies  $c^{\text{start}} = i$  and  $d^{\text{start}} = i_{\text{left}}$ , yielding  $\varphi(c^{\text{start}}) = d^{\text{start}}$ . By  $|A_P^+(i)| = |A_T^+(i_{\text{left}})|$  we know that no arc in  $A_T^+(i_{\text{left}})$  can be deleted, meaning that  $\varphi$  must map the right endpoints of the arcs  $A_P^+(i)$  to the right endpoints of the arcs in  $A_T^+(i_{\text{left}})$  bijectively. Using that  $\varphi$  is an alignment of  $(S_P; S_T)$ , it must indeed map  $c^{\text{end}}$  to  $d^{\text{end}}$ , by the definition of  $R_{\text{left}}^+(i)$ .  $\square$

*Proof (of Lemma 9).* Observe that the conditions of Lemma 8 hold for every proper marked fragmentation obtained by the algorithm, in particular for  $\mathcal{F}$ .

First, suppose that the conditions of (i) hold, and suppose  $a < b$  (the case  $a > b$  is analogous). As  $a$  is a trivial position not marked in  $(\mathcal{F}, M)$ , claim (1) of Lemma 8 implies  $|A_P^+(a)| = |A_T^+(a_{\text{right}})|$ . Let  $c$  be an arc  $(a, b)$  and let  $(c, d) \in R_{\text{right}}^+(a)$ . As  $a$  is trivial, it is right-aligned as well, so we obtain  $\varphi(b) = \varphi(c^{\text{end}}) = d^{\text{end}}$  by Lemma 3. Using claim (2) of Lemma 8 for  $a$ , we also know  $d^{\text{end}} = b_{\text{right}}$ . This implies  $\varphi(b) = b_{\text{right}}$ , showing that  $b$  is indeed right-aligned.

Assume that the conditions of (ii) hold for  $a$  and  $b$ . As both of them are left-aligned, we get that  $A_P(a, b)$  must equal the number of arcs connecting  $a_{\text{left}}$  and  $b_{\text{left}}$  in  $A_T \setminus A^{\text{del}}(\varphi)$ . Hence, if  $A_P(a, b) > A_T(a_{\text{left}}, b_{\text{left}})$  then we reject, and if  $A_P(a, b) < A_T(a_{\text{left}}, b_{\text{left}})$  then we output a removable arc  $(a_{\text{left}}, b_{\text{left}})$ .  $\square$

To prove Lemmas 7 and 8, we start with the observations of Lemma 13, stating that the properties ensured during some step will not be violated later on. This has important consequences regarding the correctness of the algorithm (which are used in the proofs of Lemmas 7 and 8), but in addition, it provides a convenient tool that can be used for bounding the running time.

**Lemma 13.** *Let  $\mathcal{F}'$  be a fragmentation obtained from  $\mathcal{F}$  by dividing some  $F \in \mathcal{F}$  into fragments  $F_1$  and  $F_2$  with a right split (with  $F_1$  preceding  $F_2$ ). Let  $1 \leq \ell \leq 8$ .*  
*(1) Suppose  $i$  is not contained in  $F_2$  and  $\ell \neq 7$ . If Property  $\ell$  holds for  $i$  in  $\mathcal{F}$  (or in  $\mathcal{F}^{\text{rev}}$ ), then Property  $\ell$  holds for  $i$  in  $\mathcal{F}'$  (or in  $\mathcal{F}'^{\text{rev}}$ ) as well.*  
*(2) Suppose  $\pi(\mathcal{F}, H, \ell) = 1$  for a fragment  $H$ . If  $H \neq F$  then  $\pi(\mathcal{F}', H, \ell) = 1$ , and if  $H = F$  then  $\pi(\mathcal{F}', F_1, \ell) = 1$ .*

- (3) Suppose  $\pi(\mathcal{F}^{\text{rev}}, H^{\text{rev}}, \ell) = 1$  for a fragment  $H \in \mathcal{F}$ . If  $H \neq F$  then  $\pi(\mathcal{F}'^{\text{rev}}, H^{\text{rev}}, \ell) = 1$ , and if  $H = F$  then  $\pi(\mathcal{F}'^{\text{rev}}, F_1^{\text{rev}}, \ell) = 1$ .  
(4) If  $\pi(\mathcal{F}^{\text{rev}}, F^{\text{rev}}, \ell) = 1$ , then  $\pi(\mathcal{F}'^{\text{rev}}, F_2^{\text{rev}}, \ell) = \pi(\mathcal{F}', F_2, \ell) = 1$ .  
(5) If  $(\mathcal{F}, M)$  is a proper marked fragmentation, then so is  $(\mathcal{F}', M)$ .

*Proof.* To see (1), we need some basic observations. First,  $i_{\text{left}}$  is the same according to  $\mathcal{F}'$  as it is in  $\mathcal{F}$  for each  $i$  not contained in  $F_2$ , and  $i_{\text{right}}$  is the same according to  $\mathcal{F}'$  as it is in  $\mathcal{F}$  for each  $i \in [n_P]$ . Second, the set of non-trivial positions in  $\mathcal{F}'$  is a subset of the non-trivial positions in  $\mathcal{F}$ . These conditions directly imply (1) for each case where  $\ell \notin \{5, 6, 7\}$ , using only the definitions of these properties.

Observe that if an arc in  $A_P$  is contained in  $\mathcal{L}(H'_1, H'_2)$ , for some  $H'_1$  and  $H'_2$  in the fragmentation  $\mathcal{F}'$ , then it is contained in  $\mathcal{L}(H_1, H_2)$  for some  $H_1$  and  $H_2$  in  $\mathcal{F}$  as well. The analogous fact holds also for the sets  $\mathcal{R}(H'_1, H'_2)$  and  $\mathcal{X}(H'_1, H'_2)$ . Thus, if  $i$  violates Property 5 or 6 in  $\mathcal{F}'$ , then  $i$  also violates it in  $\mathcal{F}$ , proving (1).

Clearly, (2) and (3) follow directly from (1) in the cases where  $\ell \neq 7$ . For the case  $\ell = 7$ , observe that  $\pi(\mathcal{F}, H, 7) = 1$  implies  $\mathcal{R}(H_0, H) = \emptyset$  for every  $H_0$  preceding  $H$ . Hence, the requirements of statement (2) follow immediately. The analogous claim in the reversed instance shows that (3) also holds for  $\ell = 7$ .

To prove (4), let  $i$  be contained in  $F_2$ . Note that Properties 2, 3,  $\dots$ , 8 vacuously hold for  $i$  in  $\mathcal{F}'$ , because  $F_2$  is trivial. Using that  $i_{\text{left}} = i_{\text{right}}$  and the definition of Property 1, we get that if it holds for  $i^{\text{rev}}$  in  $\mathcal{F}^{\text{rev}}$ , then it holds for  $i$  in  $\mathcal{F}'$  as well. Finally, observe that if Property  $\ell$  holds for some trivial position  $i$  in  $\mathcal{F}'$ , then it trivially holds for  $i^{\text{rev}}$  in  $\mathcal{F}^{\text{rev}}$ , proving (4).

To prove (5), assume that  $(\mathcal{F}, M)$  is proper. By (2), (3), and (4), we immediately obtain that  $(\mathcal{F}', M)$  is 8-proper, so we only have to verify Property 9. But since the set  $M$  of marked trivial positions is the same in both fragmentations, and  $i_{\text{left}}$  is the same in  $(\mathcal{F}', M)$  as in  $(\mathcal{F}, M)$  for each non-trivial or marked trivial position  $i$  of  $\mathcal{F}'$ , Property 9 also remains true for each position.  $\square$

Observe that (5) of Lemma 13 directly proves Lemma 7. Below we give a proof of Lemma 8 as well.

*Proof (of Lemma 8).* First, we show that the statements of the lemma hold for  $(\mathcal{F}, M)$ . To see this, recall that each trivial position in  $(\mathcal{F}, M)$  is marked, therefore statements (1) and (2) for  $(\mathcal{F}, M)$  are equivalent to Properties 2 and 8 for  $(\mathcal{F}^{\text{rev}}, M^{\text{rev}})$ , respectively. Since  $(\mathcal{F}, M)$  is 8-proper, these properties indeed hold for each position in  $(\mathcal{F}^{\text{rev}}, M^{\text{rev}})$ .

To see that these statements remain true after applying a sequence of right splits to  $(\mathcal{F}, M)$ , we need two simple observations. First, notice that the value of  $i_{\text{right}}$  for a position  $i \in [n_P]$  does not change in a right split. Second, the set of positions that are not marked does not change either, since the performed right splits do not modify the set  $M$  of marked positions. Thus, statements (1) and (2) for some position  $i$  have exactly the same meaning in  $(\mathcal{F}', M)$  as in  $(\mathcal{F}, M)$ . This proves the lemma.  $\square$

### C. Proving the running time of the algorithm

As a straightforward implication of the claims (1), (2), and (3) of Lemma 13, we obtain the following observation.

**Proposition 14.** *Let  $\mathcal{F}'$  be a fragmentation obtained from  $\mathcal{F}$  by performing a right split. Then  $\mu(\mathcal{F}') \geq \mu(\mathcal{F})$ .*

This will be used in the proof of Lemma 12. For technical reasons, we slightly re-formulate this lemma as follows.

**Lemma 15.** *Let  $\mathcal{F}_1, \dots, \mathcal{F}_t, \mathcal{F}_{t+1}$  be a series a fragmentations such that for each  $i \in [t]$  the algorithm obtains  $\mathcal{F}_{i+1}$  from  $\mathcal{F}_i$  by applying a left or a right split at a position  $j_i$  violating Property  $\ell_i$  in  $\mathcal{F}_i$ . Let  $H_i$  denote the fragment of  $\mathcal{F}_i$  containing  $j_i$ .*

*(1)  $\mu(\mathcal{F}_{i+1}) \geq \mu(\mathcal{F}_i)$  for each  $i \in [t]$ . If  $\mu(\mathcal{F}_{i+1}) = \mu(\mathcal{F}_i)$ , then either  $\ell_i = 2$  and the algorithm applied a left split to obtain  $\mathcal{F}_{i+1}$ , or  $\ell_i = 7$ .*

*(2) If  $\mu(\mathcal{F}_1) = \mu(\mathcal{F}_{t+1})$  and  $\ell_i = 7$  for every  $i \in [t]$ , then  $H_i$  contains every position in  $H_{i+1}$  for each  $i \in [t]$ . Also,  $t \leq k_b$  holds.*

*Proof.* First, notice that a left split is the same as a right split in the reverse instance. Also, the measure of a fragmentation is the same as the measure of its reversed version. By Proposition 14, this implies  $\mu(\mathcal{F}_{i+1}) \geq \mu(\mathcal{F}_i)$  for each  $i$ .

To prove the rest of claim (1), suppose that  $\mu(\mathcal{F}_{i+1}) = \mu(\mathcal{F}_i)$  and  $\mathcal{F}_{i+1}$  is obtained from  $\mathcal{F}_i$  by a right split at  $j_i$ . Let  $H'_i$  be the non-trivial fragment obtained from  $H_i$  in this step. Now, by the choice of  $j_i$ , Property  $\ell_i$  is violated by  $j_i$  in  $\mathcal{F}_i$ , but is not violated by any position  $j'$  preceding  $j_i$  in  $\mathcal{F}_i$ . In all cases where  $\ell_i \neq 7$ , claim (1) of Lemma 13 implies that the positions preceding  $j_i$  cannot violate Property  $\ell_i$  in  $\mathcal{F}_{i+1}$ , yielding  $\pi(\mathcal{F}_i, H_i, \ell_i) = 0$  but  $\pi(\mathcal{F}_i, H'_i, \ell_i) = 1$ . Considering claims (2) and (3) of Lemma 13, (1) follows.

To prove (2), suppose that  $H_i$  is a counterexample for (2), meaning that  $H_i$  does not contain the positions of  $H_{i+1}$ . Since  $\mathcal{F}_{i+1}$  is obtained from  $\mathcal{F}_i$  by a right split, this can only happen if  $H_{i+1}$  is a non-trivial fragment of  $\mathcal{F}_i$  different from  $H_i$ . Recall that a fragment  $B$  contains some position violating Property 7, if and only if  $\mathcal{R}(A, B) \neq \emptyset$  holds for some fragment  $A$  in the fragmentation. Hence,  $\pi(\mathcal{F}_{i+1}, H_{i+1}, 7) = 0$  implies  $\pi(\mathcal{F}_i, H_{i+1}, 7) = 0$ .

Since the algorithm always chooses the first position violating some property to branch on,  $j_i$  must be the smallest position that is LR-critical for some pair of fragments in  $\mathcal{F}_i$ . Therefore,  $H_i$  must precede  $H_{i+1}$ . But now, the choice of  $j_{i+1}$  indicates  $\pi(\mathcal{F}_{i+1}, H'_i, 7) = 1$ , where  $H'_i$  is the non-trivial fragment of  $\mathcal{F}_{i+1}$  obtained by splitting  $H_i$  at  $j_i$  in  $\mathcal{F}_i$ . Together with  $\pi(\mathcal{F}_i, H_i, 7) = 0$  and statements (2) and (3) of Lemma 13, this shows  $\mu(\mathcal{F}_{i+1}) > \mu(\mathcal{F}_i)$ , a contradiction.

It remains to show  $t \leq k_b$ . By the claim proven above,  $H_1 \in \mathcal{F}_1$  contains every  $j_i$ . Let  $\mathcal{P}$  denote the set of non-trivial fragments in  $\mathcal{F}_1$  preceding  $H$ . By the construction of the fragmentations  $\mathcal{F}_i$ , each fragment in  $\mathcal{P}$  is a non-trivial fragment of  $\mathcal{F}_i$  as well, preceding  $H_i$ . We denote by  $\mathcal{P}_{\mathcal{R}, i}$  those fragments  $F$  in  $\mathcal{P}$  for which  $\mathcal{R}(F, H_i) \neq \emptyset$  holds in  $\mathcal{F}_i$ . Since  $j_i$  is LR-critical for some pair of fragments in  $\mathcal{F}_i$ , we get  $\mathcal{P}_{\mathcal{R}, i} \neq \emptyset$  for any  $i \in [t]$ . Note also  $\mathcal{P}_{\mathcal{R}, i+1} \subseteq \mathcal{P}_{\mathcal{R}, i}$ .

For some  $F \in \mathcal{P}_{\mathcal{R},i}$ , then we define  $d^i(F)$  as follows. If  $\mathcal{L}(F, H_i) = \emptyset$  in  $\mathcal{F}_i$ , then let  $y_i^L$  be the first position contained in  $F$  minus one, otherwise let  $y_i^L$  have the value of  $L^{\max}(F, H_i)$  in  $\mathcal{F}_i$ . Also, let  $y_i^R$  be the value of  $R^{\min}(F, H_i)$  in  $\mathcal{F}_i$ . We set  $d^i(F) = y_i^R - y_i^L$ . Let  $A \in \mathcal{P}_{\mathcal{R},i+1} \cap \mathcal{P}_{\mathcal{R},i}$  be a non-trivial fragment such that  $j_i$  is LR-critical for  $(A, H_i)$ . We show  $d^{i+1}(A) > d^i(A)$ . First note that neither  $L^{\max}(A, H_{i+1}) > L^{\max}(A, H_i)$  nor  $R^{\min}(A, H_{i+1}) < R^{\min}(A, H_i)$  is possible, since  $\mathcal{L}(A, H_{i+1}) \subseteq \mathcal{L}(A, H_i)$  and  $\mathcal{R}(A, H_{i+1}) \subseteq \mathcal{R}(A, H_i)$  always hold. This implies  $y_{i+1}^L \leq y_i^L$  and  $y_{i+1}^R \geq y_i^R$ .

Clearly,  $j_i$  is either L-critical or R-critical for  $(A, H_i)$ . First, let us assume that  $j_i$  is L-critical for  $(A, H_i)$ . Observe that the definition of L-criticality implies that for any arc  $c$  starting at  $L^{\max}(A, H_i)$  and contained in  $\mathcal{L}(A, H_i)$  in  $\mathcal{F}_i$ , we know  $c^{\text{end}} \geq j_i$ . Since  $\mathcal{F}_{i+1}$  is obtained by performing the right split at  $j_i$ , every position of  $H_{i+1}$  precedes  $j_i$ , implying that such an arc  $c$  cannot be contained in  $\mathcal{L}(A, H_{i+1})$  in  $\mathcal{F}_{i+1}$ . Thus,  $L^{\max}(A, H_{i+1}) \neq L^{\max}(A, H_i)$ , from which  $y_{i+1}^L < y_i^L$  follows. Therefore, we have  $d^{i+1}(A) > d^i(A)$ .

Second, let us assume that  $j_i$  is R-critical for  $(A, H_i)$ . By the definition of R-criticality, for any arc  $c$  starting at  $R^{\min}(A, H_i)$  and contained in  $\mathcal{R}(A, H_i)$  in  $\mathcal{F}_i$ , we know  $c^{\text{end}} \geq j_i$ . Again, we know that every position of  $H_{i+1}$  precedes  $j_i$ . From this, we have that  $c$  cannot be contained in  $\mathcal{R}(A, H_{i+1})$  in  $\mathcal{F}_{i+1}$ , implying  $y_{i+1}^R > y_i^R$ . Therefore, we have  $d^{i+1}(A) > d^i(A)$  in this case as well.

Now, we claim that  $1 \leq d^i(A) \leq \sigma(A)$  for any  $A \in \mathcal{P}_{\mathcal{R},i}$ . First, it is clear that for any  $\ell < 7$ , Property  $\ell$  holds for each position both in  $\mathcal{F}_i$  and in the reversed fragmentation  $\mathcal{F}_i^{\text{rev}}$ , as otherwise the algorithm would branch on a position violating Property  $\ell$ . Thus,  $L^{\max}(A, H_i) \geq R^{\min}(A, H_i)$  cannot happen, as this would mean that there is a conflict-inducing position in  $H_i$  for  $(A, H_i)$ , violating Property 6. This directly implies  $1 \leq d^i(A)$ .

On the other hand, assume  $d^i(A) = y_i^R - y_i^L > \sigma(A)$ . This implies that  $h = y_i^R - \sigma(A)$  is contained in  $A$ , but no arc of  $\mathcal{L}(A, H_i) \cup \mathcal{R}(A, H_i)$  starts in  $h$ . However, by Properties 2 and 4 for  $y_i^R$ , we know that some arc in  $A_T^+((y_i^R)_{\text{left}}) = A_T^+(h_{\text{right}})$  ends in  $H_i$ . Using these properties for  $h^{\text{rev}}$  in the reversed instance, we obtain that some arc  $c$  in  $A_P^+(h)$  must also end in  $H_i$ . By Property 4 for  $h$ ,  $c$  must be contained in one of the sets  $\mathcal{L}(A, H_i)$ ,  $\mathcal{R}(A, H_i)$ ,  $\mathcal{X}(A, H_i)$ . But  $y_i^L < h < y_i^R$ , so we obtain  $c \in \mathcal{X}(A, H_i)$ . Therefore, some position in  $H_i$  violates Property 5, a contradiction. This proves  $1 \leq d^i(A) \leq \sigma(A)$ .

Now, observe that for any  $i \in [t]$ ,  $j_i$  is LR-critical for some  $(A, H_i)$  with  $A \in \mathcal{P}_{\mathcal{R},i}$ . If  $A \in \mathcal{P}_{\mathcal{R},i+1}$  as well, then  $d^{i+1}(A) > d^i(A)$ . By our bounds on  $d^i(A)$ , this yields that there can be at most  $\sigma(A)$  indices  $i$  where  $j_i$  is LR-critical for  $(A, H_i)$ . (Here we also used that  $d^i(A)$  cannot decrease.) This clearly implies  $t \leq \sum_{F \in \mathcal{P}} \sigma(F) = \delta(H_1)$ . Finally,  $\delta(H_1) \leq k_b$  proves (3).  $\square$

*Proof (of Lemma 11).* Let us briefly overview the steps of our algorithm. We start from an initial marked fragmentation  $MF_0$ . While the marked fragmentation is not proper, we choose the smallest  $\ell$  and the smallest position  $i$  violating Property  $\ell$  (maybe in the reversed instance), and branch into a bounded number of directions. In these branches, we either modify the actual marked fragmentation, output a **removable base**, or **reject**. We proceed with such branchings

iteratively until we either produce an output, or we obtain a proper fragmentation. After this, we do not perform any more branchings. Instead, we apply Lemma 9 repeatedly. In each such step, we either **reject**, output a **removable arc**, or perform a right split. If we reach a state where Lemma 9 does not apply, then we output an **arc-preserving alignment** using Lemma 10.

Let us bound the size of the search tree created by the algorithm. First, observe that those branchings where we guess  $\varphi(i)$  for some position  $i$  result in at most  $k_b + 1$  directions. Such branchings will be called *standard branchings*. Recall that additional branchings only occur when  $i$  turns out to be left aligned, and Lemma 6 yields Cases D or E. Branchings caused by Case D can occur at most  $k_b - 1$  times, and each such branching results in at most  $k_b - 1$  directions. Case E produces at most  $2k_b - 1$  branches, each yielding an output immediately, so this can only happen once.

We are going to show that the number of standard branchings is at most  $g(k_a, k_b) = 4k_b^3 + 17k_b^2 + 2k_b k_a = O(k_b^3 + k_b k_a)$ . This implies that the height of the search tree is at most  $f(k_a, k_b) + k_b$ , and it has at most  $f(k_a, k_b) = (k_b + 1)^{g(k_a, k_b)} (k_b - 1)^{k_b - 1} (2k_b - 1) = k_b^{O(k_b^3 + k_b k_a)}$  leaves. To verify that each branch can be performed in linear time, it suffices to show that we spend only  $O(|(S_T, A_T)|)$  time in each node. For this, the only non-trivial task is to show that the repeated application of Lemma 9 can be implemented in linear time. But since Lemma 9 cannot be applied more than twice for an arc  $(a, b) \in A_P$ , this iteration can indeed be implemented in  $O(|(S_T, A_T)|)$  time.

It remains to bound the number of standard branchings performed in a row. Let  $MF_0, MF_1, \dots, MF_t$  be the sequence of marked fragmentations produced in this process. (We interpret these as marked fragmentations for  $\varphi$  and not for  $\varphi^{\text{rev}}$ .) We are going to show  $t \leq g(k_a, k_b)$ . We say that two marked fragmentations  $MF_i$  and  $MF_j$  are in the same *segment*, if they have the same number of non-trivial fragments. By Lemma 2, this divides the sequence  $MF_0, \dots, MF_t$  into at most  $k_b$  segments. Let  $\mathcal{S} = MF_{t_1}, MF_{t_1+1}, \dots, MF_{t_2}$  be such a segment. Clearly, either  $MF_h$  ( $t_1 < h \leq t_2$ ) is obtained by a left or a right split from  $MF_{h-1}$ , or  $MF_h^{\text{rev}}$  ( $t_1 < h \leq t_2$ ) is obtained by a left or a right split from  $MF_{h-1}^{\text{rev}}$ . Let  $MF_p$  be the last marked fragmentation in  $\mathcal{S}$  that is not 8-proper.

Let the measure of a marked fragmentation be the measure of its fragmentation. Using Lemma 12, we know that  $\mu(MF_h) < \mu(MF_{h+1})$  must hold for any  $t_1 \leq h < p$ , except for the following two possibilities. First,  $\mu(MF_h) = \mu(MF_{h+1})$  can happen if  $MF_{h+1}$  is obtained from  $MF_h$  by performing a left split at a position violating Property 2 (Case B of Lemma 6). Recall that this can happen at most  $2k_a$  times. Second,  $\mu(MF_h) = \mu(MF_{h+1})$  can happen if  $MF_{h+1}$  is obtained from  $MF_h$  by performing a right split at a position violating Property 7. By (2) of Lemma 12, this can happen for at most  $k_b$  consecutive branchings. Taking into account that the number of non-trivial fragments cannot exceed  $k_b$ , but branchings can also happen in the reversed instance, Lemma 12 also implies that there can be at most  $2k_b$  continuous sequences of such branchings. This shows that  $\mu(MF_h) = \mu(MF_{h+1})$  can happen altogether for at most  $2k_b^2 + 2k_a$  indices

$h$  with  $t_1 \leq h < p$ . Using again Proposition 2 and that  $MF_p$  is not 8-proper, we get  $\mu(MF_p) \leq 16k_b - 1$ . Hence, we obtain that  $p - t_1 \leq 2k_b^2 + 16k_b + 2k_a - 1$ .

Now, we consider the marked fragmentations  $MF_{p+1}, MF_{p+2}, \dots, MF_{t_2}$  (if existent) obtained by the algorithm while trying to ensure Property 9. Observe that  $MF_{h+1}$  ( $p+1 \leq h < t_2$ ) is obtained by applying a right split at  $j$ , so by the choice of  $j$ , Property 9 holds for each position  $j' \leq j$  in any  $MF_{h'}$  where  $h' \geq h$ . Note that this strongly relies on the fact that the set of marked positions does not increase in these right splits, since we do not mark the new trivial positions. This, together with Proposition 2 implies that we can perform at most  $k_b$  such branchings, yielding  $t_2 \leq p+1+k_b \leq t_1+4k_b^2+17k_b+2k_a$ . Altogether, this implies that each segment can contain at most  $4k_b^2 + 17k_b + 2k_a$  standard branchings, which proves our claimed bound on the size of the search tree.  $\square$
